1. Introduction

The OpenAS2 application enables you to transmit and receive AS2 messages with EDI-X12, EDIFACT, XML, or binary payloads between trading partners. The AS2 implementation conforms with [RFC4130](#).

This document describes how to install, configure and use OpenAS2. In this document a partner can be either your own company or a company you will be exchanging data with using AS2.

The sample configurations in this document are based on Unix type OS but in general the only significant difference is that it may be necessary to use “\” instead of “/” for folder name separators on Windows based machines but because the application is Java it should work fine leaving the “/” for the most part as Java will do the conversion if necessary.

This document is valid for version 1.3.7 and up.

2. Glossary

EDI – Electronic Data Interchange

MDN - Message Disposition Notification

3. Installing OpenAS2

To be able to run the OpenAS2, you will need:

1. Java™ installed on the machine you intend to run the OpenAS2 server on – this document uses Java 1.6.
2. The OpenAS2 package version you wish to use. The downloadable packages can be found here: <https://sourceforge.net/projects/openas2/files>
3. Java Cryptography Extension (JCE) policy files - you can download the correct version from the Java website. Search “Java Cryptography Extension Unlimited Strength” to find the right cryptography extension for your version of Java. The current link for Java8 is [here](#).

The following steps will provide an installed app on a target machine:

1. Unzip the downloaded OpenAS2 package into a suitable location, which we will call `<install_dir>`.

NOTE: Typical values for `<install_dir>` locations are `/opt/OpenAS2` under Linux®/Unix or `C:\OpenAS2` under Microsoft® Windows®.

2. For the encryption and certificate management to work correctly, you must have the proper JCE policy files installed in your version of Java. The downloaded zip archive contains the two files `local_policy.jar` and `US_export_policy.jar`. Install them into your Java location under `<JAVA_HOME>/lib/security`. Back up the existing files before installing these new ones. There are numerous detailed articles on the web for installing these files if you need more information.

The file structure will look something like the figure below without the data and logs folders which are created automatically by the server when it starts based on configuration if they do not exist.

Name	Date Modified	Size	Kind

4. Configuration

This section explains the details of the configuration files and how they link together.

The OpenAS2 server uses four files to configure and execute:

1. config.xml – configures the application
2. partnerships.xml – configures the partners
3. as2_certs.p12 – stores the PKCS12 certificates for all partners
4. commands.xml – stores the commands that the application will support. This file should not be modified

IMPORTANT: A restart of the application is required to load any configuration changes.

The folder containing the config.xml file defines the **home** configuration parameter that can be used to reference other files on the file system relative to a known base folder in the app. This is done by encapsulating **home** in percentage signs (**%home%**). All files can be referenced relative to this parameter and it is how the default config.xml file defines the location of other configuration and data file locations used by the OpenAS2 application.

4.1. Application Configuration

The file named “config.xml” configures the modules that will be activated by the AS2 server when it starts up. This file can be located anywhere within the disk subsystem on which the OpenAS2 application runs as it is passed into the application as a startup parameter.

Some of the key configuration settings in the config.xml file are:

- define the modules to be activated in the OpenAS2 application
- override module default classes in the AS2 code base
- enhance or change behaviour of modules and the inputs and outputs of the modules.
- define the location of the certificates keystore and password
- define the location of the partnerships configuration file
- specify the listening ports

See appendices for a detailed definition of the config.xml file structure.

There are 2 listening ports for inbound connections (see partnerships.xml config for outbound connections) used for:

1. receiving messages and synchronous MDN's – default port number 10080
2. receiving asynchronous MDN's - default port number 10081

The port numbers are arbitrary and defaulted to a number above 1024 that does not require root access to listen on (normally on Unix type systems any port below 1024 requires root access). The port values are important to the partner you will be communicating with if they will be sending AS2 messages to your system. For outbound only systems, it is only necessary to have a listener for asynchronous MDN's if using that mechanism for MDN's.

Each module has a number of attributes that can be configured on the module element to control and change how the module behaves.

4.1.1. Overriding Certificate Store Password

The certificate store password is stored as an XML attribute “password” on the <certificates> element. This can be overridden using the system property “**org.openas2.cert.Password**”. For improved security, it may not be desired to store the password in the XML file.

This can be passed into the application by adding the following to the java command:

- **-Dorg.openas2.cert.Password=myCertificateStorePassword**

This can be set by using an additional parameter to the batch script file so that it can be set as part of invoking the script. The UNIX shell script will support the password as a parameter. The Windows bat file will need to be enhanced.

4.1.2. Resend Retry Configuration

When failures occur transferring a message to a trading partner, the system will automatically try to resend the message. By default the system will retry indefinitely.

Restricting the retry attempts can be done at the processor level (applies to all partnerships configured on the server) and at the partnership level. Partnership configuration will override processor settings.

To define the processor level retry count, set the “**resend_max_retries**” attribute on the processor element to a valid integer.

Example snippet:

```
<processor classname="org.openas2.processor.DefaultProcessor"
    pendingMDN="%home%/../data/pendingMDN3"
    pendingMDNinfo="%home%/../data/pendinginfoMDN3"
    resend_max_retries="10" >
```

To define the partnership level retry count, set an attribute element on the partnership with **name** attribute value as “**resend_max_retries**” and a **value** attribute element to a valid integer.

Example snippet:

```
<partnership name="OpenAS2A-to-OpenAS2B">
    <attribute name="resend_max_retries" value="3"/>
    <sender name="OpenAS2A"/>
```

4.2. Partner Configuration

The file named partnerships.xml configures all the information relating to the partners you will be exchanging data with. See the appendix for information on the structure of this file.

It is important to keep in mind that the word **partner** refers to any entity specified as a recipient or sender of AS2 messages and includes your own company that you might be configuring the application for.

Each partner will require the following entries in the file:

- a **<partner>** element – key information defining the partner
- a **<partnership>** element - key information for defining a partnership between 2 partners
Separate **<partnership>** elements are required for inbound and outbound data for a specific partner pairing.

NOTE: It is not necessary to have 2 elements if data transfer is unidirectional.

4.2.1. Partner Definition

The **<partner>** element requires 3 attributes to enable AS2 partner identification:

1. partner name – this is the key to connect partnerships to a partner definition
2. AS2 identifier – this is the key for identifying the target/source partner and is included in AS2 message headers to allow the receiving partner to identify the source of the message and verify the target partner for the AS2 message. It is also used by the general directory polling module to look up the partner names and hence the partnership definition where the as2_id of the sender and receiver are part of the transferred file name.

3. X.509 certificate alias – identifies the alias of the certificates for this partner in the keystore. The encryption and decryption of messages requires the partner's public or private key as appropriate

4.2.2. Partnership Definition

The <partnership> element identifies a **specific direction** of AS2 message transfer **from** one partner **to** another. The “name” attribute on the <partnership> element is not important but should be used to clearly identify the intended use of the partnership definition. It is suggested the name value uses the names of the source and destination partners something like xxx-to-yyy.

The <partnership> element encapsulates a number of child elements that are necessary to properly configure a partnership:

- <sender name=”xxx”> - identifies the sending partner definition such that xxx must match the “name” attribute of a <partner> element
- <receiver name=”yyy”> - identifies the receiving partner definition such that yyy must match the “name” attribute of a <partner> element
- <as2_url> - a fully qualified URI that provides the connection string to the remote partner for sending AS2 messages. If sending to another OpenAS2 server then the port number must match the value configured in the config.xml file of the remote OpenAS2 server.
- <as2_mdn_to> - necessary if an MDN response is required and can be any random string but is most commonly configured with an email address

4.2.3. Transfer Encoding

As of version 1.3.7, the default content transfer encoding uses “binary” if not explicitly overwritten in the configuration. The default can be changed using the “**content_transfer_encoding**” attribute in the partnership.xml file. If you experience issues with failing to verify a partner's AS2 inbound message because the message contains CR/LF data in it then you should switch to using “binary” for the transfer encoding. The sample partnership file sets the transfer encoding to “binary” for both partners.

4.2.4. Supported Encoding Algorithms

The currently supported encoding algorithms are:

- MD5
- SHA1
- SHA224
- SHA256
- SHA384
- SHA512
- CAST5
- 3DES
- IDEA
- RC2_CBC
- AES128 (CBC mode)
- AES192 (CBC mode)

- AES256 (CBC mode)
- AES256_WRAP

4.2.5. Message Compression

The application supports inbound compression automatically. There is no configuration for this option. To enable outbound compression requires setting “**compression_type**” attribute on the partnership definition for the outbound configuration. The only supported compression/decompression at this time is “**ZLIB**”. The default is no compression of sent messages.

By default compression will occur on the message body part prior to signing. The compression can be configured to occur after signing using the “**compression_mode**” attribute on the partnership definition for the outbound configuration. Set the attribute to “**compress-after-signing**” to enable this.

See partnership.xml appendix for configuration details.

4.3. Certificate Configuration

The certificate store used by default is a PKCS12 key store and stores all X.509 certificates.

The key store must contain the private key of your own X.509 certificate and the public key for each of your trading partners X.509 certificates.

The certificates must be stored with the matching alias as specified in the partner definition of each partner in the partnership.xml file.

There is a shell file to help generating certificates: **bin/gen_p12_key_par.sh**

An excellent open source visual keystore manager that will run on any OS can be found here:

<http://portecle.sourceforge.net/>

4.4. Logging System

Logging supports 6 levels that can be controlled by configuration. The logging output can be directed to multiple destinations including:

- System console
- Local log files
- Email – log messages are emailed to a configured email address.
- Socket – log messages are written to a socket supporting remote logging

All log classes can be overridden or custom logger classes can be coded and included via configuration

4.4.1. Log Level Configuration

The logging system supports the use of either or both the **commons-logging.properties** file or a file named **openas2log.properties** to control the logging level. Properties in openas2log.properties will override commons-logging.properties entries. There is a commons-logging.properties file in the **bin** directory which is part of the classpath specified in the script file described in the section on running the application.

The properties in the **openas2log.properties** file should be prefixed by **“org.openas2.logging.”**

The following are the logging levels supported by the application in order of lowest(finest) to highest:

"TRACE", "DEBUG", "INFO", "WARN", "ERROR", "FATAL"

The logging levels are turned off by specifying the level you want on and all other levels higher than that level will also be turned on.

The default level is INFO and therefore WARN, ERROR and FATAL are also turned on by default. By adding a property level=DEBUG in the common-logging.properties file will result in DEBUG logging being enabled along with INFO, WARN, ERROR and FATAL

The same can be achieved by adding org.openas2.logging.openas2log.level=DEBUG in the openas2log.properties file.

4.4.2. Email Logging Configuration

The email logger uses the javax mail API to send ERROR level log messages. Some of the basic email configuration parameters are supported via config in the config.properties file as indicated in the appendix. The rest of the mail properties as listed in the Javamail API can be set by passing them as system properties on the command line by modifying the start-openas2.sh or start-openas2.bat file as appropriate or using the **javax.mail.properties.file** attribute on the email logger element.

The configuration values can overwrite each other depending on the source of the configuration value. The order of priority is as follows:

1. values set in the logger element attributes
2. entries in the file identified by **javax.mail.properties.file**
3. entries using system properties

For example, to pass the port for connection you could add this to the command line:
-Dmail.smtp.port=529

To point to a properties file containing all the relevant information you would add something like this:

```
<logger classname="org.openas2.logging.EmailLogger"
    javax.mail.properties.file="%home%/java.mail.properties"
    from="openas2"
    ...
```

4.5. MDN Configuration

MDN's can be sent synchronously or asynchronously. By default the system will use synchronous MDN mechanism. Per the AS2 specification, an MDN will only be sent on receipt of an AS2 message if the **“Disposition-Notification-To”** header is present in the received message with a non-empty value. Although this value is specified to be configured with an email address, it is not utilized for any purpose in the AS2 protocol other than to indicate an MDN is required so can in fact be any random string. To set the **“Disposition-Notification-To”** header in an outbound message, the **“as2_mdn_to”** attribute must be set on the partnership.

The other attribute that must be set is the **“as2_mdn_options”**. This defines the encryption algorithm and other MDN settings as specified by the AS2 protocol and the value entered for this attribute will be sent in the **“Disposition-Notification-Options”** header of the AS2 message.

Generally changing the encryption algorithm to suit the trading partner should be sufficient on this attribute.

4.5.1. Asynchronous MDN Receiver Configuration

In order to specify an asynchronous MDN response from a partner requires setting the following attribute on the partnership element in the partnership configuration:

- **as2_receipt_option** – set to the URL of the asynchronous MDN receiver to target the asynchronous MDN receiver module configured in the config file (ie. this is the URL that the partner will send the MDN to). The value set in this attribute will be sent in the **“Receipt-Delivery-Option”** header of the AS2 message to the trading partner. For testing using the default config file that comes with the OpenAS2 installation package, set this to: <http://localhost:10081>

Receiving an asynchronous MDN requires the **“AS2MDNReceiverModule”** module. This module declaration requires a port parameter in addition to the class and can be entered as a child member of the processor node in the config file as shown below:

```
<module classname="org.openas2.processor.receiver.AS2MDNReceiverModule" port="10081" />
```

4.5.2. Asynchronous MDN Sender Configuration

Sending an asynchronous MDN requires the **“AsynchMDNSenderModule”** module. This module declaration does not require any parameters other than the class and can be entered as shown below as a child member of the processor node in the config file:

```
<module classname="org.openas2.processor.sender.AsynchMDNSenderModule" />
```

4.6. Configuring HTTPS Transport

HTTPS transport using SSL is configured separately for inbound and outbound connectivity.

4.6.1. Inbound Transfers

Configuration for inbound is in the config.xml file. The requirements for receiving AS2 files using HTTPS are:

- JKS keystore containing the SSL certificate
- an appropriately configured As2ReceiverModule module element

The key attributes that configure HTTPS are:

- **protocol**="https"
- **ssl_keystore**="%home%/ssl_certs.jks" – points to the JKS certificate keystore
- **ssl_keystore_password**="<passwordforkeystorefile"
- **ssl_protocol**="TLS"

See the appendix for details on the attributes.

4.6.2. Outbound Transfers

The partnership definition for the connection URL will also have to be set to the appropriate host name.

The key attributes that configure HTTPS are:

- `as2_url`
- `as2_mdn_to` (only if MDN is required)

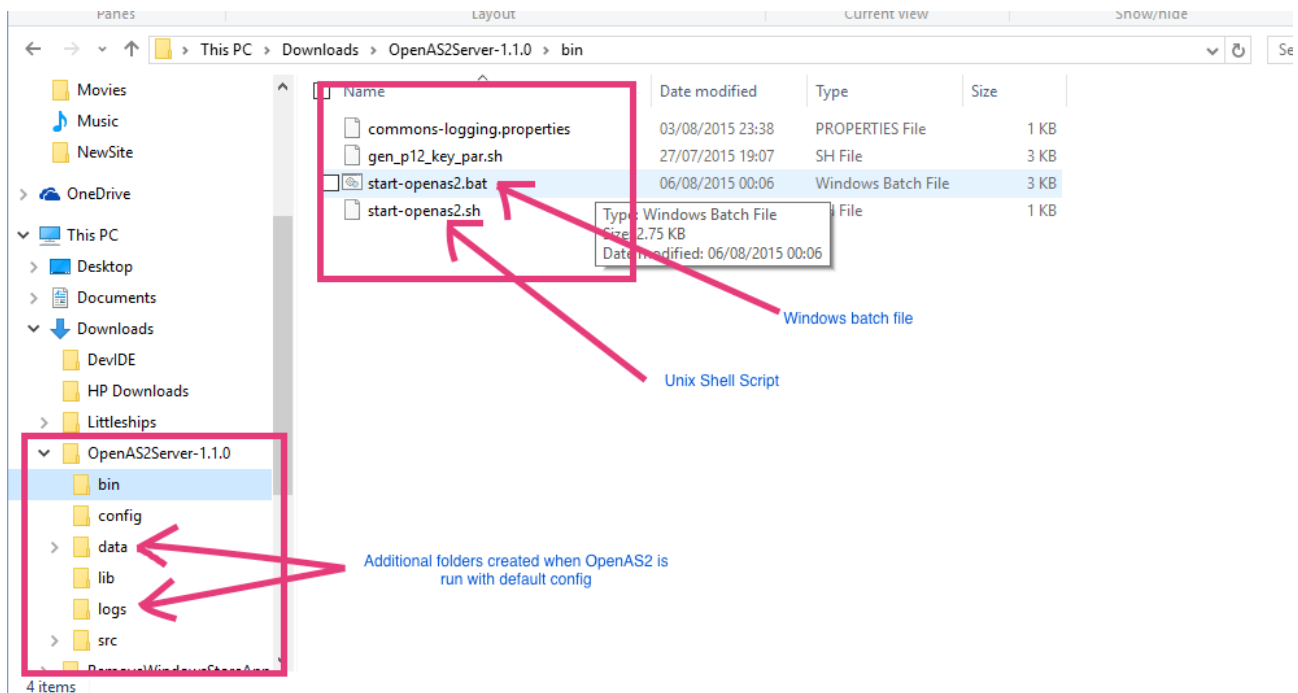

If asynchronous MDN is in use and requires HTTPS then a **As2MDNReceiverModule** module needs to be configured in the same way as for the `As2ReceiverModule` class above.

If the target system being connected to uses self signed certificates, the following system property will have to be passed to the application in the java command line with a comma separated list (no spaces before or after comma) of the “Common Name” (CN) in the self signed certificate that will be returned by the target system:

```
-Dorg.openas2.cert.TrustSelfSignedCN=<Common.Name1>,<Common.Name2>,...
```

5. Running OpenAS2

The default install of the application is as in the figure below from a windows PC.

There are 2 executable script files in the **bin** folder of the AS2 application root as indicated in the screenshot above:

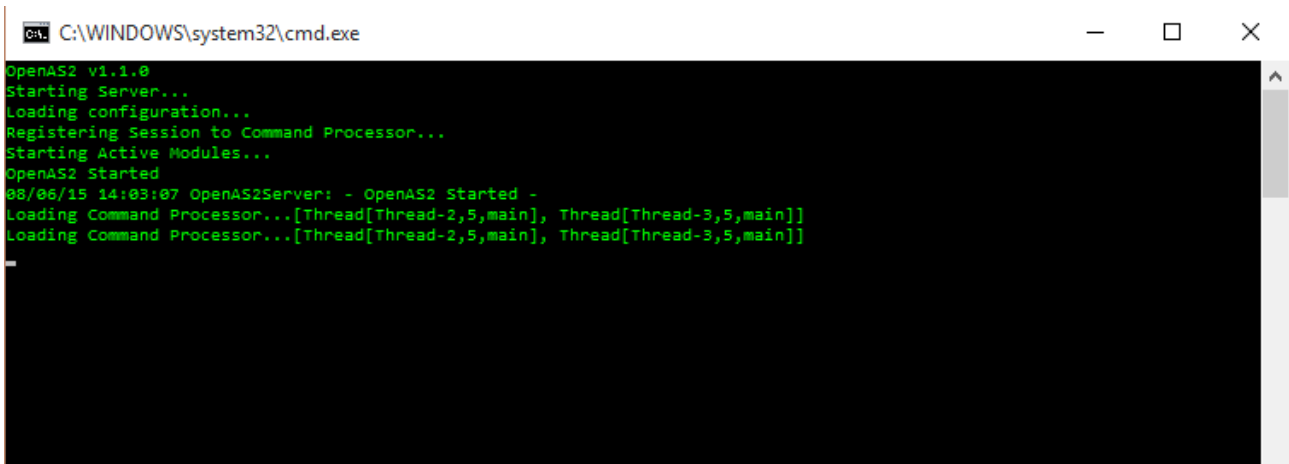

1. `start-openas2.sh` – for UNIX based systems
2. `start-openas2.bat` – for Microsoft Windows based system

It is not necessary to modify these files for the default install to work. If you choose to put the `config.xml` file in a different location than the default then you will need to edit the appropriate script file and set the path to the `config.xml` file appropriately.

Simply execute the script file and an AS2 server will start up. It will create the following folders along with sub folders when it starts assuming no change to the default config:

- logs – contains the normal program logging
- data – contains all the transferred files and any AS2 specific headers associated with AS2 transfers. This folder will have a number of sub folders for outbound and inbound files for different partners

In Microsoft Windows you should be able to double click the start-openas2.bat file and a command window will open as below.

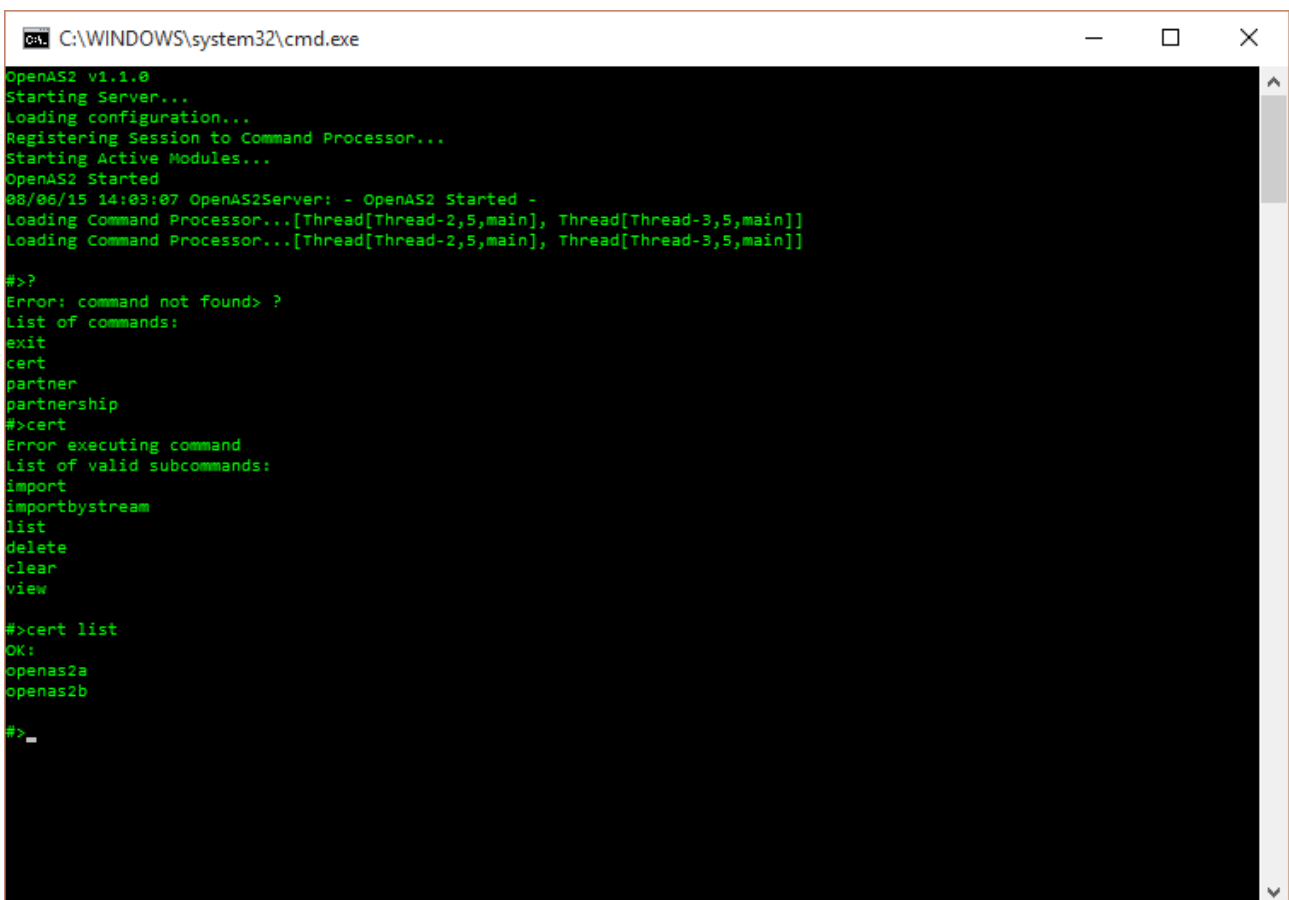

```

C:\WINDOWS\system32\cmd.exe
OpenAS2 v1.1.0
Starting Server...
Loading configuration...
Registering Session to Command Processor...
Starting Active Modules...
OpenAS2 Started
08/06/15 14:03:07 OpenAS2Server: - OpenAS2 Started -
Loading Command Processor...[Thread[Thread-2,5,main], Thread[Thread-3,5,main]]
Loading Command Processor...[Thread[Thread-2,5,main], Thread[Thread-3,5,main]]

```

No command prompt is shown initially but you can enter a command or just press <ENTER> to get a visible prompt. Typing ? Will show possible commands. Each command will list sub commands they require if you try to enter them without the appropriate parameters. A sample is shown below.

```

C:\WINDOWS\system32\cmd.exe
OpenAS2 v1.1.0
Starting Server...
Loading configuration...
Registering Session to Command Processor...
Starting Active Modules...
OpenAS2 Started
08/06/15 14:03:07 OpenAS2Server: - OpenAS2 Started -
Loading Command Processor...[Thread[Thread-2,5,main], Thread[Thread-3,5,main]]
Loading Command Processor...[Thread[Thread-2,5,main], Thread[Thread-3,5,main]]

#>?
Error: command not found> ?
List of commands:
exit
cert
partner
partnership
#>cert
Error executing command
List of valid subcommands:
import
importbystream
list
delete
clear
view
#>cert list
OK:
openas2a
openas2b
#>_

```

There will be some logging as the application starts and it will then provide a command prompt (you may need to press the ENTER key to see it due to logging events).

You can enter commands after startup by typing in the console window.

For Unix based systems such as Linux and OSX, open a terminal window and change directory to the “bin” folder of the install. The start_openas2.sh file should have execute permissions in which case simply type the name and press enter. If no execute permissions are set, either set the execute permission as needed or use “sh” to run the script:

```
/opt/OpenAS2:>sh opensas2.sh
```

The output in a Unix based system will be identical to that in a Windows based system.

6. Testing OpenAS2 Transfers

The default configuration of the OpenAS2 configuration is set up for two partners named “OpenAS2A” and “OpenAS2B”. The system will effectively send messages to itself between the 2 configured partners. You can simply start the OpenAS2 server without any changes and then copy a file into the appropriate outbox as defined by the relevant module using the org.openas2.processor.receiver.AS2DirectoryPollingModule classes “**outboxdir**” attribute to send the file to the desired partner.

The default configuration provides for 2 partners OPENAS2A and OPENAS2B and will create outbox folders `<installDir>/data/toOpenAS2A` and `<installDir>/data/toOpenAS2B` for explicitly targeting a partner for any file dropped in one of those folders.

If you wish to run 2 OpenAS2 servers on the same machine then the ports on the 2nd instance of OpenAS2 as configured in the config.xml must be different to those configured on the first instance (see Application Configuration above). If using asynchronous MDN, the URL entry for the attribute “**as2_receipt_option**” in the partnerships.xml file for the 2nd instance must match the values configured in the 1st instances config.xml for host name and port and vice-versa.

6.1. Using HTTPS Transport

To test on a local machine using the supplied sample self signed SSL certificate (config/ssl_certs.jks) you should create a localhost DNS entry. The sample certificate was generated for “www.openas2.localhost”.

This site will help in how to set up a local DNS:

http://www.selfsignedcertificate.com/development_tips.php

The As2ReceiverModule module element should be configured correctly. The key attributes that will work with the supplied sample certificate are already in the sample config file and should just be uncommented:

- `protocol="https"`
- `ssl_keystore="%home%/ssl_certs.jks"`
- `ssl_keystore_password="testas2"`
- `ssl_protocol="TLS"`

The partnership definition for the connection URL will also have to be set to the appropriate host name and use “https” instead of “http”:

```
<attribute name="as2_url" value="https://www.openas2.localhost:10080"/>
```

If asynchronous MDN is used then the as2_receipt_option attribute must be configured for SSL as well:

```
<attribute name="as2_receipt_option" value="https://www.openas2.localhost.com:10081"/>
```

The following system property will have to be passed to the application in the java command line:

```
-Dorg.openas2.cert.TrustSelfSignedCN=www.openas2.localhost
```

If you experience problems with SSL, try adding this to the startup command in the script file:

```
-Djavax.net.debug=SSL
```

7. Troubleshooting OpenAS2

Experience has shown that not all systems properly implement the AS2 specification or have an interpretation of the specification that is different to the OpenAS2 default implementation. To accommodate these differences, the OpenAS2 application has some configuration parameters to change the default behaviour on a per partnership basis that may help to accommodate the implementation anomalies for various other AS2 systems.

7.1. Canonicalization For MIC Algorithm

Some systems (including OpenAS2 prior to V1.3.7) do not canonicalize the MimeBodyPart as specified in the RFC when content transfer encoding is not “binary” (the OpenAS2 default is “binary” but can be set to other values using the “**content_transfer_encoding**” attribute on the partnership). This manifests as errors that cause signature authentication failure that may specifically mention a mismatched MIC. To cater for this set the following attribute on the partnership:

```
<attribute name="prevent_canonicalization_for_mic" value="true"/>
```

7.2. Binary Encoding

If using a content transfer encoding algorithm other than “binary” results in authentication failures, try setting the attribute on the partnership:

```
<attribute name="content_transfer_encoding" value="binary"/>
```

7.3. Java Versions Prior To 1.6

Prior to java 1.6, the Javabeans Activation Framework is NOT included in the standard Java install. Download the 1.1.1 version and extract from the zip file from this web page:

<http://www.oracle.com/technetwork/java/javasebusiness/downloads/java-archive-downloads-java-plat-419418.html#jaf-1.1.1-fcs-oth-JPR> 

The activation.jar must be placed into the “lib” folder of the OpenAS2 server install and added to the class path in the shell or batch file as appropriate.

8. Remote Control

By default the OpenAS2 server application will start up a command processor as a socket listener allowing remote connection to the OpenAS2 server to execute commands. The OpenAS2 remote application is part of the application package but is not necessary to use it if you have no remote access requirement and should be disabled in the config.xml file if not using it by removing or commenting out the **<commandProcessor>** element with classname value

org.openas2.cmd.processor.SocketCommandProcessor

You can set the port that the command processor listens on using the **portId** parameter.

<commandProcessor

classname="org.openas2.cmd.processor.SocketCommandProcessor" portId="14321"
userid="userID" password="pWd"/>

The remote control application will need to connect to the specified port with the specified user ID and password.

The connection uses an anonymous secure socket cipher and may require changing this if your Java implementation does not support the default cipher which is

TLS_DH_anon_WITH_AES_256_CBC_SHA for the latest release. This cipher is not available in older Java versions and it may be necessary to switch to SSL_DH_anon_WITH_RC4_128_MD5

To switch cipher you will need to start the OpenAS2 server and the remote command client passing the cipher name as a system property using the -D switch that can be added to the batch script that starts the application. The property must be named “**CmdProcessorSocketCipher**”.

e.g java -D**CmdProcessorSocketCipher=SSL_DH_anon_WITH_RC4_128_MD5** ...

9. Dynamic Variables

Variables can be used in configuration files for real time replacement of strings. Some variables are specific to certain processor modules. The variables used in the configuration files are as follows:

\$date.xxx\$::: for date parameters

where xxx is any valid character formatting string defined in

java.text.SimpleDateFormat

for example: **\$date.YYYY\$** gets the four digit year

\$msg.xxx.yyy\$, accesses various information about the incoming message, used by MessageFileModule. The available options for this format of dynamic variable are:

1. **\$msg.sender.as2_id\$** - retrieves the AS2 ID of the sender of the message
2. **\$msg.receiver.as2_id\$** - retrieves the AS2 ID of the receiver of the message
3. **\$msg.attributes.yyy\$** - used to access any attribute on the message where the attribute identifier is used in place of “**yyy**”
for example
4. **\$msg.headers.yyy\$** - used to access any header on the message where the header identifier is used in place of “**yyy**”
5. **\$msg.content-disposition.yyy\$** - used to access any content-disposition attribute in the

message content disposition where the attribute identifier is used in place of “yyy”
Some attributes commonly found in an AS2 message content disposition include

- filename – the original name of the file that was sent
-

\$mdn.zzz\$ for message mdn parameters, used by EmailLogger and MDNFileModule
where zzz can be any of the following values to get

- msg – requires “zzz” to be in the form “xxx.yyy” and can access data points as defined for \$msg.xxx.yyy\$ format dynamic variables above
- sender – gets the as2_id of the sender
- receiver – gets the as2_id of the receiver
- text – gets the text portion of the MDN
- attributes – requires “zzz” to be in the form “xxx.yyy” and can access data points as defined for \$msg.xxx.yyy\$ format dynamic variables above
- headers – requires “zzz” to be in the form “xxx.yyy” and can access data points as defined for \$msg.xxx.yyy\$ format dynamic variables above

for example: *\$mdn.text\$* gets the text portion of the MDN

\$exception.xxx\$, used by EmailLogger

where xxx can be any of the following values to get

- name
- message
- trace
- terminated

for example: *\$exception.trace\$* gets the trace log of the exception

10. Appendix: config.xml file structure

- Node: **openas2**
 - Node: **certificates**

Attributes

classname

describes the Java class to process the certificate file.

for example: *org.openas2.cert.PKCS12CertificateFactory*

filename

defines the file name containing the certificates

for example: *%home%/certs.p12*

password

opens the file using this password

for example: *test*

*NOTE: this can be overridden using a java system property
when starting the application:*

-Dorg.openas2.cert.Password=<somePassword>

interval

describes how often the file should be check up for updates. Specified in seconds.
for example: 300

- Node: **partnerships**

Describes the OpenAS2 classes to handle the trading partner identifications.

Attributes

classname

describes the Java class to process the partnerships file

for example: *org.openas2.partner.XMLPartnershipFactory*

defines the file name containing the partnerships definitions

describes

for example: *%home%/partnerships.xml*

- Node: **loggers**

Describes the OpenAS2 logging classes to use. **You must include**

-Dorg.apache.commons.logging.Log=org.openas2.logging.Log in your startup call or as a property in the commons-logging.properties file. See

<http://commons.apache.org/logging/guide.html#commons-logging-api.jar> for more information.

Do not use this node when using other logging packages (e.g. log4j) with the OpenAS2 package.

- Node: **logger** (for E-mail logging)

Optional, if not specified no E-mail logging is performed.

Attributes

classname

describes the Java class to process E-mail logging

for example: *org.openas2.logging.EmailLogger*

show (Optional)

describes what level of logging to handle

Possible values

- all = all exceptions (terminated or not) and info
- terminated = all terminated exceptions **Default value**
- exceptions = all non-terminated exceptions

for example: *terminated*

from

defines the source email address

for example: *logger@openas2.org*

from_display

defines the displayed text of the source email address

for example: *Openas2*

to

defines the recipient email address

for example: *your@e-mailaddress.com*

smtpserver

describes the SMTP server to process outgoing e-mail
for example: *mySillyMailerDot.com*

smtpport

defines the SMTP server port to connect to
for example: 587

smtpauth

defines whether authentication is required for the SMTP server
(Possible values: true, false)
for example: true

smtpuser

defines user name if authentication is required for the SMTP
server

smtppwd

defines user password if authentication is required for the SMTP
server

subject

describes the e-mail to the receiving party
for example: *\$exception.name\$: \$exception.message\$ (only
relevant a specific exceptions type)*

bodytemplate

defines the file that contains the body of the message
for example: *%home%/emailtemplate.txt*

- Node: **logger** (for file logging)

Optional, if not specified no file logging is performed.

Attributes

classname

describes the Java class to log messages
for example: *org.openas2.logging.FileLogger*

filename

defines the name of the output log file.
for example: *%home%/log-\$date.MMddyyyy\$.txt*

show (Optional)

describes what level of logging to handle

Possible values

- all = all exceptions (terminated or not) and info **Default value**
- terminated = all terminated exceptions
- exceptions = all non-terminated exceptions
- info = all info log entries

for example: *terminated*

- Node: **logger** (for Console logging, writes to System.out)

Optional, if not specified no console logging is performed.

Attributes

classname

describes the Java class to log messages
for example: *org.openas2.logging.ConsoleLogger*
show (Optional)

describes what level of logging to handle

Possible values

- all = all exceptions (terminated or not) and info **Default value**
- terminated = all terminated exceptions
- exceptions = all non-terminated exceptions
- info = all info log entries

for example: *info*

- Node: **commands**

Describes the OpenAS2 command classes to use

Attributes

classname

describes the Java class to process the command file

for more information see [Command File](#)

for example: *org.openas2.app.XMLCommandRegistry*

filename

defines the name of the file command all possible commands

for example: *%home%/commands.xml*

- Node: **processor**

Describes the OpenAS2 class to handle the message processors.

Attributes

classname

describes the default Java class to handle outgoing message

for example: *org.openas2.processor.DefaultProcessor*

- Node: **module**

Module that sends out AS2 messages.

Attributes

classname

describes the Java class to send outgoing Messages

for example: *org.openas2.processor.sender.AS2SenderModule*

retry

defines the number of attempts for sending a message, default is -1 aka infinite.

for example *retries="3"* will stop sending the message after 3 failures.

connecttimeout

defines the millisecond count before a connection times out.

default value is 30000 or 30 seconds.

for example *connecttimeout="60000"* will time out after 60 seconds.

readtimeout

defines the millisecond count before a read times out. default value is 30000 or 30 seconds.
for example *readtimeout="60000"* will time out after 60 seconds.

- Node: **module**

Module that sends out AS2 MDNs asynchronously.

Attributes

classname

describes the Java class to send asynch MDN

for example:

org.openas2.processor.sender.AsynchMDNSenderModule

retry

defines the number of attempts for sending a message, default value is -1 (infinite.)

for example *retries="3"* will stop sending the message after 3 failures.

connecttimeout

defines the millisecond count before a connection times out. default value is 30000 or 30 seconds.

for example *connecttimeout="60000"* will time out after 60 seconds.

readtimeout

defines the millisecond count before a read times out. default value is 30000 or 30 seconds.

for example *readtimeout="60000"* will time out after 60 seconds.

- Node: **module**

The following will describe a module to process outgoing message placed in a generic directory. The module determines the receiver and send from the file name placed in the directory (see [format](#) attribute). This module will look for files in specified directory and file names to send to the default message processor.

Attributes

classname

describes the Java class to process files to be sent to the AS2SenderModule for its delivery process.

for example:

org.openas2.processor.receiver.AS2DirectoryPollingModule

outboxdir

defines the directory where files are to be found.

for example: *%home%/toAny*

fileextensionfilter

defines the extension of the file name if file filtering is required. The system will prefix the text entered in this attribute with a period and only files matching that extension will be picked up by the polling module

for example: txt - *this will only find files like test.txt but not*

mytxt

errordir

defines directory where files containing errors are redirected to.
for example: *%home%/toAny/error*

interval

describes how often the directory is to be checked for work.
Specified in seconds. Default is 30 seconds.
for example: 5

delimiters

defines the characters used to parse the incoming file name.
Characters are separate the tokens: sender, receiver and file id.
for example: -.

format

describes the file name by the tokens sender, receiver and file id.
May be in any order. Sender id and receiver id are as defined in
the partnership.xml file.
for example: *sender.as2_id, receiver.as2_id, attributes.fileid*
or *attributes.mimetype, attributes.mimesubtype, sender.name,*
receiver.name

mimetype

describes the outgoing message mime message type.
for example: *application/EDI-X12*

- Node: **module**

Attributes

classname

describes the Java class to process files for a particular trading
partner that are sent to the AS2SenderModule for its delivery
process.
for example:
org.openas2.processor.receiver.AS2DirectoryPollingModule

outboxdir

defines the directory where outgoing message are defined.
for example: *%home%/toOpenAS2A/*

errordir

defines the directory where erroneous messages are left.
for example: *%home%/toOpenAS2A/error*

interval

describes how often the incoming directory is searched. Defined
in seconds, default is 30 seconds.
for example: 5

defaults

describes the AS2 sender and receiver ids as defined in the
partnership.xml file.
for example: *defaults="sender.as2_id=OpenAS2A_OID,*
receiver.as2_id=OpenAS2B_OID"

protocol

describes the AS2 protocol, which is AS2.
for example: *as2*

mimetype

describes the outgoing message mime message type.

for example: *application/EDI-X12*

- Node: **module**

Attributes

classname

describes the Java class to process incoming MDNs

for example: *org.openas2.processor.storage.MDNFileModule*

filename

describes

for example: *%home%/mdn/\$date.yyyy\$/\$date.MM\$/\$mdn.msg.sender.as2_id\$-\$mdn.msg.receiver.as2_id\$-\$mdn.msg.headers.message-id\$*

protocol

describes

for example: *as2*

tempdir

describes

for example: *%home%/temp*

- Node: **module** Defines the module to handle messages.

Attributes

classname

describes the Java class to process and store incoming messages

for example:

org.openas2.processor.storage.MessageFileModule

filename

describes the location and formatted filename of the stored MDNs.

for example: *%home%/inbox/\$msg.sender.as2_id\$-\$msg.receiver.as2_id\$-\$msg.headers.message-id\$*

protocol

describes the AS2 protocol

for example: *as2*

tempdir (Optional)

defines temporary directory used to store MDNs during message processing.

for example: *%home%/temp*

- Node: **module**

Attributes

classname

describes the Java class to process handle incoming transfers

for example:

org.openas2.processor.receiver.AS2ReceiverModule

port

defines the port the server listens on.

for example: *10080*

errordir

defines directory where invalid incoming messages are stored.

for example: *%home%/inbox/error*

errorformat
 defines the format of filenames for invalid incoming messages.
 for example: *sender.as2_id, receiver.as2_id, headers.message-id*

protocol
 optional and defaults to “http” if not present
 set to “https” for SSL transport protocol

ssl_protocol
 optional and defaults to “TLS” if not present
 set to preferred SSL transport protocol
 for example: SSLv3

ssl_keystore
 The name of the file including path containing SSL certificate
 only required for “protocol” attribute set to “https”
 for example: *%home%/ssl_certs.jks*

ssl_keystore_password
 The password to open the SSL keystore
 only required for “protocol” attribute set to “https”
 for example: *mySecretPassword*
NOTE: this can be overridden using a java system property when starting the application:
-Dorg.openas2.sslPassword=<somePassword>

- Node: **module**

Attributes

classname
 describes the Java class to send asynchronous MDN response
 for example:
org.openas2.processor.receiver.AS2MDNReceiverModule

port
 defines the port the server listens on.
 for example: *10080*

protocol
 optional and defaults to “http” if not present
 set to “https” for SSL transport protocol

ssl_protocol
 optional and defaults to “TLS” if not present
 set to preferred SSL transport protocol
 for example: SSLv3

ssl_keystore
 The name of the file including path containing SSL certificate
 only required for “protocol” attribute set to “https”
 for example: *%home%/ssl_certs.jks*

ssl_keystore_password
 The password to open the SSL keystore
 only required for “protocol” attribute set to “https”
 for example: *mySecretPassword*
NOTE: this can be overridden using a java system property when starting the application:
-Dorg.openas2.sslPassword=<somePassword>

- Node: **module**

Attributes

classname

describes the Java class to rehandle messages
for example:

org.openas2.processor.resender.DirectoryResenderModule

resenddir

defines the directory to find message to resend
for example: *%home%/resend*

errordir

defines the director to store resend messages that are in error.
for example: *%home%/resend/error*

resenddelay

defines the wait time between resends. Defined in seconds.
Default is 60.
for example: *600*

11. Appendix: *partnership.xml* file structure

This file describes your company and your trading partners. This file requires modification to work with your application

- Node: **partnerships**

The root node.

- Node: **partner**

partner definition

Attributes

name

partner name as defined in OpenAS2 configuration file.
OpenAS2A

as2_id

partner name as defined in partnership node
OpenAS2A

x509_alias

Alias as defined in certificate file
openas2a

email

E-mail address of partner
as2a@MySillyMailerServer.com

- Node: **partnership**

defines partner relationships between sender and receiver

- Node: **partnership**

Attributes

name

Unique name of partnership relation. See filename parsing above.

OpenAS2A-OpenAS2B

- Node: **sender**

Attributes

name

Unique name of Sender

OpenAS2A

- Node: **receiver**

Attributes

name

Unique name of receiver

OpenAS2B

*The following is a list of nodes that use the node name of **attribute**. The subnodes of **attribute** use a name/value node naming pair structure.*

- Node: **attribute**

name is **protocol** defines the protocol to use with this partner.

value is **as2**

name="protocol" value="as2"

- Node: **attribute**

name is **subject** defines text used in E-mail subject line

value

name="subject" value="From OpenAS2A to OpenAS2B"

- Node: **attribute**

name is **as2_url** defines partners AS2 server's URL

value

name="as2_url" value="http://www.MyPartnerAS2Machine.com:10080"/>

- Node: **attribute**

name is **as2_mdn_to** when set this specifies that an MDN response is

required and defines value of the "**Disposition-Notification-To**" header in the AS2 message sent to the partner. It is normally an email address but can be any string that is meaningful

value

name="as2_mdn_to" value="datamanager@mypartner.com"

- Node: **attribute**

name is **as2_receipt_option** defines asynchronous MDN server's URL

value

name="as2_receipt_option" value="http://www.MyAS2Machine.com:10081"

- Node: **attribute**

name is **as2_mdn_options** defines MDN option values for E-mail header

value

name="as2_mdn_options" value="signed-receipt-protocol=optional, pkcs7-signature; signed-receipt-micalg=optional, sha1"

- Node: **attribute**

name is **encrypt** defines encrypting algorithm name for E-mail header
value

name="encrypt" value="3des"

- Node: **attribute (optional)**

name is **content_transfer_encoding** defines what the header field should display

value 8bit (default), binary, ...

name="content_transfer_encoding" value="binary"

- Node: **attribute (optional)**

name is **compression_type** if defined it determines what the type of compression to use. Leave this attribute out if no compression is required

value ZLIB (default) – no other supported options

name="compression_type" value="ZLIB"

- Node: **attribute (optional)**

name is **compression_mode** if defined it determines when compression occurs. If this attribute is not specified then compression occurs before signing.

value – “compress-after-signing”

name="compression_mode" value="compress-after-signing"

12. Appendix: command.xml file structure

List of commands available to the OpenAS2 server Application.

- Node: **commands** the root node

- Node: **multicommand**

attribute

name

value "cert|part", certificate commands or partnership commands

description

value is some useful text

- Node: **command**

attribute

classname

value is a OpenAS2 classname that will process a command
